Resumen

The number of municipalities (9) that make part of Intermunicipal Community of Terras de Trás-os-Montes (IMC-TTM) hence the dispersed and although diachronic different geographical information systems (GIS) existing solutions, plus the responsibilities of intermunicipal communities (combined authorities) in different domains, set a compelling need for the implementation of an intermunicipal spatial data infrastructure (SDI) that allow the availability of updated and interoperable geographic information.

In this context, IMC-TTM implemented a SDI in open source software, working as a single, uniformed central repository, transversal to the municipalities, allowing a greater effectiveness and efficiency of local governments in the management and development of the territory.

If IMC-TTM SDI should facilitate access to geographic information - assure efficiency and effectiveness of territorial decisions, adopt European and national policies, industry standards (OGC standards), joint work methodologies, define and use common data models, have a unique SDI access point to all users, eliminate data duplication and allow the optimization of data maintenance tasks -, then we have adopt a solution based on geOrchestra framework and have installed it. It's an open, modular, interoperable and secure software solution that allows the registration of the different stakeholders and access through different user profiles. The first part of this paper presents the four phases of the project implementation, coming up with some lessons for helping future efforts of IMC-TTM and other inter-municipal communities that are developing similar projects. In the second part of the paper the technical solution is described.

Abstract

El número de municipios (9) que forman parte de la Comunidad Intermunicipal de Terras de Trás-os-Montes (IMC-TTM), por lo tanto, las soluciones existentes dispersas y aunque diacrónicas de Sistemas de Información Geográfica (SIG), más las responsabilidades de las comunidades intermunicipales (autoridades combinadas) en diferentes dominios, establecen una necesidad apremiante para la implementación de una infraestructura de datos espaciales intermunicipal (IDE) que permita la disponibilidad de información geográfica actualizada e interoperable.

En este contexto, IMC-TTM implementó una IDE en software de código abierto, trabajando como un repositorio central único y uniformado, transversal a los municipios, permitiendo una mayor efectividad y eficiencia de los gobiernos locales en la gestión y el desarrollo del territorio.

Si la IDE IMC-TTM debe facilitar el acceso a la información geográfica, asegurar la eficiencia y efectividad de las decisiones territoriales, adoptar políticas europeas y nacionales, estándares industriales (estándares OGC), metodologías de trabajo conjuntas, definir y usar modelos de datos comunes, tener un punto de acceso IDE único para todos los usuarios, eliminar la duplicación de datos y permitir la optimización de las tareas de mantenimiento de datos; se ha adoptado una solución basada en el framework geOrchestra y se ha instalado. Es una solución de *software* abierta, modular, interoperable y segura que permite el registro de las diferentes partes interesadas y el acceso a través de diferentes perfiles de usuario.

La primera parte de este documento presenta las cuatro fases de la implementación del proyecto, presentando algunas lecciones para ayudar a los esfuerzos futuros de IMC-TTM y otras comunidades intermunicipales que están desarrollando proyectos similares. En la segunda parte del documento se describe la solución técnica.

1. INTRODUCTION AND CONTEXT

A spatial data infrastructure (SDI) can be defined as a system of systems composed of a set of very heterogeneous resources (data, software, hardware, metadata, services, standards, staff, organization, legal framework, agreements, policies, users ...), managed by a community of stakeholders, to share geographic information (GI) on the web in the most effective way possible [1]. This definition is one of several definitions of SDI that can be found in the literature. For municipalities and intermunicipal communities (combined authorities), one of the most important issue in the SDI definition is the possibility of easily overcome the traditional problems of geographic information systems (GIS) implementations in municipalities. The overcoming of these problems implies a paradigm change in the use and management of geographic information.

Considering the responsibilities of intermunicipal communities in different domains, the implementation of intermunicipal SDIs that allow the availability of updated and interoperable geographic information is a necessity to decide properly on the territory.

In this context, the Intermunicipal Community of Terras de Trás-os-Montes (IMC-TTM) has developed a SDI, in open software, working as a single, uniformed central repository, transversal to the municipalities, allowing a greater effectiveness and efficiency of local governments in the management and development of the territory.

If IMC-TTM SDI should facilitate access to geographic information, assure efficiency and effectiveness of territorial decisions, adopt European [3] and national policies [2]; industry standards (OGC standards), joint work methodologies, define and use common data models, have unique SDI access to all users, eliminate data duplication and allow the optimization of data maintenance tasks, then become obvious that a solution based on geOrchestra framework [6] was a good solution and should be installed.

The geOrchestra technology solution was chosen for IMC-TTM's SDI implementation based on the following principles: use open source software, incorporate OGC standards [4] and INSPIRE Directive [3], universal access to information, and ensure project sustainability.

The first part of this paper presents the four phases of the project implementation, coming up with some lessons for helping future efforts of IMC-TTM and other inter-municipal communities that are developing similar projects. In the second part of the paper the technical solution is described. This description includes the SDI framework overview, the software architecture, main functionalities and the data publication workflow.

2. PROJECT IMPLEMENTATION

The implementation of the IMC-TTM SDI took place in four phases, which are presented in the following points.

2.1. PHASE I

The first phase corresponded to the diagnosis of the existing information, definition of the scope and the set of layers to include in IMC-TTM SDI and includes three main tasks. This phase began with the diagnosis of the information in use by IMC-TTM and the availability assessment of existing management and storage systems. The next task was the elaboration of a technical report with a SWOT analysis to define the intermunicipal SDI implementation strategy. The report starts with the AS IS approach where the following items were analyzed: assessment of the technological infrastructure, analysis of the GIS software and existing applications, diagnosis of the existing geographic information and the diagnosis of the needs and priorities of IMC-TTM departments. The second part of the report is the TO BE approach. This part of the report includes a proposal over the following items: the support infrastructure, the information editing/maintenance matrix, the functional architecture, the application architecture, the data model, the nomenclature layers rules and the organization of metadata.

Regarding the results of the SWOT analysis, the following strengths were identified: qualified human resources with experience in FOSS; several GIS projects prepared and published on the Internet; extension of the IMC-TTM competences with implications for the management of shared geographic information; existence of a collaborative context and availability of technological infrastructure (hardware and software) for the development of the SDI. The identified weaknesses were: different realities in the management of geographical information between the municipalities; the geographical information in the municipalities is not centralized; the geographical information in the municipalities is not shared; the procedures for updating and maintaining the geographical information in IMC-TTM database by the municipalities are not explicit; the organization and systematization of geographic information in the database is not explicit; existence of duplication of themes and temporary themes or results of processing; network bandwidth with limitations to serve geographic information on the Internet; absence of domain in the LAN and existence of outdated base cartographic information. The opportunities for the development of the project are: strong motivation; scale gains associated with the number of municipalities involved; common geographical information needs arising from legal obligations; existence of a common project

containing the strategic guidelines for intermunicipal SDI and financial support available on an intermunicipal scale. The threats to the project development are: budget constraints; resistance to change; effort duplication in geographic information maintenance; absence of human resources in some municipalities in GIS; absence of data dissemination and sharing policy; lack of responsibilities definition for maintaining geographic information and lack of a domain server. Considering the strengths, weaknesses, opportunities and threats identified, the following strategy (Table 1) was designed:

The last task of this phase consisted in the structuring and organization of metadata to meet the INSPIRE directive. For the structuring and organization of the IMC-TTM SDI metadata, the GeMA application (Azores Metadata Manager) was initially used, followed by its publication and availability through Geonetwork.

2.2. PHASE II

The second phase of the project was the physical implementation of spatial data infrastructure in open software and includes two tasks. The first task was the definition of SDI catalogue, storage and data sharing model. The second task was to install the software and configure the SDI components. The underlying principles were the following: the database management system should be Postgres / Postgis; the geoprocessing services should ensure data access and editing and support for WMS and WFS services with metadata developed and updated; each municipality should visualize the geographical information of the adjacent territory, but may only be allowed to edit for the information it owns; the IMC-TTM should be the system administrator holding all the permissions for configuration, database design, performance monitoring, security, troubleshooting, as well as backup and data recovery.

2.3. PHASE III

The third phase of the project was the insertion of information into the database. The information integrated in the database was mostly the information covered by the existing databases and their reuse, avoiding generating duplication and / or incoherence of information. The information initially inserted in the database was the following: vectorial cartography at 1/2,000, 1/5,000 and 1/10,000 scales; master plans geographic information; existing infrastructures such as water supply and wastewater drainage; public transport circuits and school transport circuits; information from the forest fire plans, hazard maps, road network, water points and other geographic information on existing public facilities.

The layers provided by municipalities, when possible, were harmonized, adopting national data models associated with legal standards (eg master plans, forest fire plans and emergency plans) or INSPIRE data models (eg toponymy, infrastructures, equipment's). This harmonization process was carried out using the HALE tool.

The layer organization for the development of an intermunicipal SDI is a critical point since it establishes the easiness of access and maintenance. For the development of the IMC-TTM SDI, the following model was used to organize the layers (Figure 1):

This model is characterized by the separation of municipal management layers into different schemas in a single geographic database (IMC-TTM SDI database). The municipal and intermunicipal layers are stored in the schemas through the tables nomenclature standardization.

2.4. PHASE IV

To proceed to the transfer of knowledge to IMC-TTM technicians and municipalities, two training actions (on the functional level and in the maintenance of the solu-

Table 1. IMC-TTM SDI implementation strategy.

| STRATEGY (Strengths Opportunities)	STRATEGY (Weaknesses Opportunities)
Development of a multi-year training plan focused on the management / maintenance component of the SDI geographic information Establishment of implementation priorities and linking these priorities to harmonized data models (eg tourism, heritage, etc.)	Separation of the production environment from the development environment Functional Architecture should preferably be based on a maintenance approach through browser tools Migration of existing data to a harmonized
STRATEGY (Strengths Threats)	STRATEGY (Weaknesses Threats)
Accountability of users in maintaining data through the publication of sectoral projects on the Internet Development of workshops by municipality focused on the management / maintenance component of the SDI geographic information Development of a regional seminar to present results (involving municipalities) Quality certification of the IMC-TTM GIS department	Implementation of open source technical and application solutions Implementation of an open data policy Definition of operational procedures that ensure the updating of geographical information and the accountability of services Provision of technical support to municipalities in sectoral projects to be developed (involving the expansion of the SDI)

Figure 1. Layers organization

One of the main reasons associated with the geOrchestra solution is the ability to manage permissions that can be assigned to users. Given the inter-municipal character of the SDI, there's the need to include users of several entities with different levels of access. For instance each municipality visualizes the geographical information of the adjacent territory but can only have edit permissions for the information it owns. These conditional access resulted in the following user profiles:
- Super Admin - IMC-TTM;
- Admin - IMC-TTM;
- Master User - IMC-TTM;
- Basic User - IMC-TTM;
- Admin – Municipality;
- User – Municipality;
- User – Citizen.

tion) were carried out. The training actions were directed to IMC-TTM users, municipalities users, IMC-TTM SDI administrators and municipalities administrators. The training actions themes were: management of profiles and users; publication of data in Geoserver; visualization, querying and editing geographic information in map viewer; and management of metadata in Geonetwork.

3.INTERMUNICIPAL SDI CHARACTERISTICS

1.5. SDI FRAMEWORK OVERVIEW

Two open source technological options for implementing the framework of the IMC-TTM SDI have been evaluated. The following solutions were considered: GeoNode (http://geonode.org/) and geOrchestra (http://www.georchestra.org/). Although the software modules and the geographic database for the two solutions (GeoNetwork, GeoServer and PostgreSQL/PostGIS) are the same the option fell on geOrchestra mainly for the flexibility for implementing other modules. One of these new modules is the civil protection event management.

The SDI can be accessed through the following link: https://ide.cim-ttm.pt/mapfishapp/ (Fig. 2).

3.2. SOFTWARE ARCHITECTURE

The software architecture (Fig. 3) is based on different open source solutions. The servers use GNU/Linux operating system (Ubuntu), Apache as a proxy and web server and Apache Tomcat as a Java applications server to deploy the geOrchestra modules.

Next to security proxy and a single-sign-on authentication system, IMC-TTM SDI geOrchestra use the following independent and interoperable modules:
- The geographic database is PostgreSQL\ PostGIS.
- A file server for storing geographic files like shapefiles, CAD files or rasters.
- A map server for sharing geospatial data (Geoserver).
- A cache server for to cache map tiles coming from Web Map Service (Geowebcache)
- A catalog application to manage spatially referenced resources (GeoNetwork).
- A map viewer to visualize, query and edit geographic objects (Mapfish).
- A central authentication system (CAS), a security proxy and a LDAP users directory, providing shared

Figure 2. IMC-TTM SDI layout

rights management between all modules.
- An analytics module for monitoring the use of web services.

A remote desktop connection is available for all the municipalities allowing a direct connection to the central database with QGIS (desktop GIS client in IMC-TTM). Some municipalities use GIS Desktop commercial software. These municipalities use the OGC FUNCTIONALITIES

The main functionalities of the IMC-TTM SDI are the following:
- Map viewer
  - Navigation tools (zoom in, zoom out, full extend).
  - Query active layers.
  - Display coordinate system.
  - Add new layers from the catalog or a remote WMS.
  - Style editor;
  - Save or restore a list of layers using Web Map Context (WMC) files.
  - Print a map in PDF format.
- Map server
  - Allow several data connections.
  - Allow layer configuration (CRS and styles).
  - Publish layer OGC web services.
 - INSPIRE compliant OGC web services

Figure 3. IMC-TTM SDI arquitecture

- Catalog
  - INSPIRE compliant metadata profile.
  - Allow to harvest metadata records on distant catalogs.
  - INSPIRE compliant metadata.

3.4. DATA PUBLICATION WORKFLOW

One of the operational objectives of Phase I consisted in gathering the existing geographical information in the municipalities with relevance to the intermunicipal SDI. The diagnosis of the geographical information in use by the IMC-TTM and the municipalities began with a survey. After the survey, the data was formally requested to all municipalities under the premise that the information management and data sharing policy is responsibility of each municipality SDI administrator. The vectorial data was harmonized and converted to PostgreSQL using QGIS. Two base layers (orthophotomaps and street network) were made available through GeoWebCache. All the final layers were stored in the server and published using Geoserver. Those layers are organized in workspaces, using the municipality name. The last step is creating an INSPIRE metadata record in GeoNetwork and link it to the OGC services metadata (WMS, WFS). To create new layers the municipalities, access the server through a remote desktop connection. With this connection they manage their own schema in the database.

4. CONCLUSIONS

In this paper we have expressed the challenges and difficulties of a combined authority in terms of SDI implementation. Such an SDI is now serving the following purposes: centralize information in a single, uniform repository; improve the quality of information and work tools; improve the operational and business level (administrative modernization) and enable greater effectiveness and efficiency of municipalities in the management and development of the territory.

It is not yet possible to draw conclusions, since the actions designed have not yet been full implemented. However, feedback from the first year of life of the SDI by users has been positive. In IMC-TTM SDI implementation the main experience has been to understand that building a SDI is basically an organizational challenge, in which the technological implementation covers less importance than the correct comprehension of the social reality of the stakeholders [5] as verified in similar projects.

From the technical lens, geOrchestra has proved to be a flexible and robust solution for a combined

authority. One of the crucial tasks in the project has been the technical training. That project task made possible the involvement of stakeholders and the participation of a great number of municipalities. On the other hand, some municipalities never adopted the SDI framework, leaving the database empty. The main challenge to solve in these stakeholders is the lack of human resources. In this on-going project, we have verified an increased efficiency in communication between the intermunicipal and municipal levels.

Sobre los autores

Nelson Mileu

PhD in Geography - Specialization in Geographic Information Sciences at the University of Lisbon, master in Geographic Information Systems at the Instituto Superior Técnico, has a degree in Geography from the University of Lisbon. He is project manager in the company Munícipia. He teaches the disciplines of geographic information systems and webgis at the Institute of Geography and Spatial Planning of the University of Lisbon where he is also a researcher at the Center for Geographical Studies. He has developed several works in the area of geographical information systems and risk mapping, coordinating about two dozen municipal emergency plans, the regional emergency plan for civil protection and the flood risk management plan of Madeira Autonomous Region and the report on the assessment and mapping of Cape Verde's hazards for the United Nations. He has participated in several European and national projects namely: Geosmartcity - Open geo-data for innovative services and user applications towards Smart Cities; GenMob - Gender and Mobility Space-Time Inequality; Decentralization and Optimization of IoT aware business processes (DoIT); and more recently in the mapping study of Erasmus + higher education networks.

Diogo Vieira

He has a degree in Electronic Engineering and Telecommunications from the University of Aveiro in 2005. Actually is a software developer in Municipia, SA, having participated in several projects such as, CECANG - Census of wholesale commercial establishments in Angola, SiNERGIC – Portuguese National System for Exploration and Management of Cadastral Information, SNC - Timor-Leste National System of Cadastral Information, GeoSmartCity - Open geo-data for innovative services and user applications towards Smart Cities. His areas of interest are related to the development of web and mobile gis solutions, based on GIS Open Source technologies, which meets the specifications of the Open Geospatial Consortium (OGC) standards.

Paulo Morgado

Paulo Morgado has a BA in Geography and Regional Planning, a Master in Geographic Information Systems and a PhD in Geography-Regional and Urban Planning. He is currently an Assistant Professor at the Institute of Geography and Spatial Planning (IGOT) at the University of Lisbon where he teaches and coordinates the subjects of: Geographical Modeling, Thematic Cartography, Planning and Territory Management, and the subjects of GIS Project and Geographic Modeling and Complex Urban Systems, in the Master of Geographic Information Systems and Territorial Modeling Applied to Planning. He is also a researcher and member of the Scientific Council of IGOT's Center for Geographical Studies (CEG) and member of the research group "Modeling, Planning and Territorial Planning" (MOPT). At present, Paulo is also a coordinate of the GeoModLAB (Laboratoy of Remote Sensing, analysis and geographic modeling).

His research areas are limited to Applied Geography, Theoretical and Quantitative Geography, with special emphasis on: Geographical Information Science, Geocomputation, Complex networks and Graph Theory, Artificial Neural Networks, Cellular Automata and Multi-Agent Systems. More recently, it has focused on Smart Cities and Big Data issues (in particular with regard to methods of acquisition, storage, analysis and availability of information). About the work pu-

blished in these areas can consult the following addresses: http://www.ceg.ul.pt/investigadores.asp?id=46

André Vargas

André Vargas has a BA in Geography, and is finishing the Master's Degree in Geographical Information Systems and Modelling applied to Spatial Planning in the Institute of Geography and Spatial Planning (IGOT) at the University of Lisbon.

Manuel Miranda

Manuel Miranda has a degree in Civil Engineering. Was a substitute teacher at Mirandela Secondary School from 1984 to 1987. Integrates the Technical Support Office as a Civil Engineer in 1987. Actually and since year 2000, he is the secretary-general of Association of Municipalities of Terra Quente Transmontana and makes part of the intermunicipal executive secretary of Comunidade Intermunicipal das Terras de Trás-os-Montes.

Hélia Pineu

Has a degree in Environmental Engineering. At present working at Association of Municipalities of Terra Quente Transmontana GIS Department is leading the Comunidade Intermunicipal das Terras de Trás-os-Montes SDI project. From 2000 to the present date work with geographic information systems. Responsible for the creation and implementation of a intermunicipal multidisciplinary GIS team and framework, using open source technologies at AMTQT. Responsible for the development of a GIS database for the Vale do Tua Regional Natural Park (PNRVT). Was integrated in the multidisciplinary team for the development, creation and implementation of a Spatial Data Infrastructure (SDI) and a platform for providing information to the municipal civil protection for the Trás-os-Montes Intermunicipal Community (ICTTM). Coordination of an intermunicipal forest protection team to support the preparation of the municipal forest fire plans and creation of the forest fire risk maps for the municipalities of Alfândega da Fé, Carrazeda de Ansiães, Macedo de Cavaleiros, Mirandela and Vila Flor. Responsable for a multidisciplinary team for the development and creation of a GIS system for the Public Transportation System for the ICTTM.

Paula Costa

Has a degree in Survey Engineering. At present is working at Association of Municipalities of Terra Quente Transmontana GIS Department and is an active member of the Comunidade Intermunicipal das Terras de Trás-os-Montes SDI project. From 2000 to the present date work with geographic information systems. Participated in the creation for the creation and implementation of a intermunicipal multidisciplinary GIS team and framework, using open source technologies in 2014 at AMTQT. Participation in the development of a GIS database for the Vale do Tua Regional Natural Park (PNRVT). Integration in the multidisciplinary team for the development, creation and implementation of a Spatial Data Infrastructure (SDI) and a platform for providing information to the municipal civil protection for the Trás-os-Montes Intermunicipal Community (ICTTM). Participation of an intermunicipal forest protection team to support the preparation of the municipal forest fire plans and creation of the forest fire risk maps for the municipalities of Alfândega da Fé, Carrazeda de Ansiães, Macedo de Cavaleiros, Mirandela and Vila Flor. Participation in a multidisciplinary team for the development and creation of a GIS system for the Public Transportation System for the ICTTM

Carlos Sousa

Started functions as a Informations Technology Technician at the municipality of Mirandela from 2001 until 2013. From 2014 to the present date as a Informations Technology Technician at the Association of Municipalities of Terraquente Transmontana (AMTQT) as part of a team that supports the metropolitan area network of Terraquente Transmontana. Intergrated a workgroup for the conversion of geografical information systems (GIS) proprietary systems to their opensource equivalents in 2009 at Mirandela municipality. Integrated a workgroup that was responsible for the assignment of the municipality towards a certificated municipality regarding the ISO9001/2008 in 2012 at Mirandela Municipality. Responsable for the creation and implementation of a intermunicipal multidisciplinary GIS team and framework, using opensource technologies at in 2014 at AMTQT. Responsable for the creation of a GIS framework to the Vale do Tua Regional Natural Park (PNRVT). Integration in a multidisciplinary team for the development, creation and implementation of a Spatial Data Infrastructure (SDI) for the Intermunicipal Community of Terras de Trás-os-Montes (ICTTM). Responsible for the creation of the publication of the municipal plans for the Forest Defense in 2015 at AMTQT. Integration in a multidisciplinary team for the development and creation of a GIS system for the Public Student Transportation System in 2016 for the ICTTM.

Hugo Trigo

Hugo Trigo has a degree in Civil Engineering. Actually he is working in Associação de Municípios da Terra Fria do Nordeste Transmontano and is an active member of the Comunidade Intermunicipal das Terras de Trás-os-Montes SDI project.
